

Problems and Fixes

We had some small and some big problems. Most of them were basically that we forgot brackets or where we put the statements or that we forgot to assign scripts to objects. One major problem was that we sometimes did not notice that we were in the game mode resulting in the fact that we needed to do everything again. So basically there were more problems of how to use unity than the actual coding because we first needed to understand how everything works.

Some problems and how We solved them can be seen in our commits to github.

Lena had problems with the blender and that the fire extinguishers were displayed differently in the blender than in unity. By rendering and using the correct materials and meshes she solved the problem in blender. But the import into Unity was after a lot of internet research not possible since Unity does not support the import of shader nodes created in blender.

Another problem was that we thought it would be nice to have an additional message which gets displayed if you use the wrong extinguisher for the wrong fire. The problem was that the text did not get deleted if the object was already collected again. She solved the problem by skipping the normal Coroutine and adding the display text manually such that we still could have the normal coroutine for the normal case of displaying the messages by hovering over the items in the inventory.

One of my major problems was the inventory and that randomly items were deleted or dropped out of the inventory but the items were not displayed again. It turned out that instead of the equals() function I just had to use "==" . Another thing where I needed a lot of time was actually how I could take the value of the timer for the time needed and the respective text of the timer and display it in the new win scene. I solved the problem by adding TMPPro objects in the trigger menu and building a small wintimer script where I could give the win scene the text which was created in the game scene.

And finally, the biggest problem was to set up a github repository and how we needed to prepare the folder such that only the needed things get cloned and not every time the whole project. Aka we missed the section about the .gitignore file.

But as you hopefully see, we worked our way around it and managed to understand GitHub a little bit better than before.
